METHOD AND CIRCUIT FOR OPTIMIZING POWER CONSUMPTION IN A FLIP-FLOP

Cross Reference to Related Applications

The present application is related to application Serial No. _____-
(RPS920020090US1/2491P), filed on even date herewith, and entitled "Circuit for
preserving Data in a Flip-Flop and a Method of Use."

Field of the Invention

[0001] The present invention relates to logic circuits, and more particularly to a method
and circuit for optimizing power consumption in a flip-flop.

Background of the Invention

[0002] Most VLSI designs have numerous flip-flops integrated within them. Typically,
flip-flops are critical to the overall performance of this design. Conventional flip-flops
are generally large, power hungry and a significant amount of time is spent optimizing
their configuration. It is desirable therefore to minimize the power used by flip-flops
in a circuit design. It is known that one way to save power is to shut off sections of the
design. For example, one way to save power is to utilize clock gating to disable the
clock when it is not used. Also, in an effort to save or minimize standby power, some
designs have resorted to disabling non-used sections of the design from the power
supply. However, disabling power supply generally results in a loss of stored data in
the volatile memory elements.

[0003] A solution for the problem of data loss during a standby mode is to transfer the
data, or state of a latch, to an on-chip memory before the latch is disconnected from
the power supply. Examples of on-chip memory include DRAM, SRAM, or Flash

memory. This enables the powering down of the latch to conserve power. This technique, however, requires an auxiliary device, i.e., the on-chip memory.

[0004] Accordingly, what is needed is a method and circuit for optimizing power consumption in a flip-flop. The method and circuit should also be cost effective, save space, and easily implemented in existing circuit designs. The present invention addresses such needs.

Summary of Invention

[0005] A flip-flop is disclosed. The flip-flop includes a first latch for receiving at least one bit and a second latch coupled to the first latch for storing the at least one bit from the first latch. The size of the second latch is minimized to reduce power consumption. The flip-flop also includes a multiplexor coupled to the first latch and to the second latch for outputting the at least one bit from the first latch when a clock to the multiplexor is active and for outputting the at least one bit from the second latch when the clock is inactive.

[0006] A system and method in accordance with the present invention optimize power consumption in a flip-flop through the use of a multiplexor for the output function. As a result, the size of the slave latch can be minimized, which reduces the overall power consumption of the flip-flop and its associated clock tree.

Brief Description of Drawings

[0007] FIG. 1 is a block diagram of a conventional master-slave flip-flop.

[0008] FIG. 2A is a block diagram of a master-slave flip-flop in accordance with the present invention.

[0009] FIG. 2B is a timing diagram showing the operation of master-slave flip-flop of FIG. 2A.

Detailed Description

[0010] The present invention relates to logic circuits, and more particularly to a method and circuit for optimizing power consumption in a flip-flop. The following description is presented to enable one of ordinary skill in the art to make and use the invention

and is provided in the context of a patent application and its requirements. Various modifications to the preferred embodiment and the generic principles and features described herein will be readily apparent to those skilled in the art. Thus, the present invention is not intended to be limited to the embodiment shown but is to be accorded the widest scope consistent with the principles and features described herein.

[0011] FIG. 1 is a block diagram of a conventional master-slave flip-flop (FF) 8. The FF 8 includes a master latch 10 and a slave latch 12. In operation, the master latch 10 receives data (labeled "data"), a clock pulse C1, and a clock set pulse C1B. The slave latch 12 receives a clock pulse C2 and a clock set pulse C2B. The slave latch 12 outputs the data (labeled "L2out"). The clock pulse C1 is driven by a clock C1, and the clock pulse C1B is driven by a clock C1B. Similarly, the clock pulse C2 is driven by a clock C2, and the clock pulse C2B is driven by a clock C2B.

[0012] With regard to performance, there are set-up criteria for the master latch and launch criteria for the slave latch. The most performance critical objective of a slave configuration is the slave latch's launch time. The objective is to minimize the time needed to transfer data from the master latch 10 to the slave latch 12. Various latching configurations can be employed, but all generally use a write-thru-read approach. That is, the architecture of the slave latch 12 is such that it stores the incoming data while it is outputting the data. For more performance, the device sizes of the slave latch 12 are generally large enough to support high-speed data transfer. As such, the large device sizes result in increased capacitance and larger area, hence they consume more power.

[0013] FIG. 2A is a high-level block diagram of the FF 100 in accordance with the present invention. The FF 100 includes a master latch 110, a slave latch 112, and a multiplexor 114. As is seen, X, Y and Z nodes are identified. The actual configuration of the master latch 110 and the slave latch 112 can vary and will depend on the specific embodiment. In this embodiment, the multiplexor 114 is a shunt multiplexor.

[0014] Because the slave latch 112 does not serve a performance-critical function, it can be implemented utilizing minimum sized devices. By minimizing the size of the devices within the slave latch, the leakage current and the operating current is

significantly reduced as compared to the larger conventional slave latch. As a result, the overall power consumption of the FF 100 is optimized.

[0015] FIG. 2B is a timing diagram showing the various signals of FF 100 of FIG. 2A. As is seen, clock C1 is shown as a first waveform, clock C2 is shown as a second waveform, and data is shown as a third waveform. As is also seen, the waveforms of the X, Y and Z nodes are shown. Referring now to both FIGS. 2A and 2B together, when the data is received by the master latch 110, it is passed to node X when the clock C1 goes high. The data is received by both the slave latch 112 and the multiplexor 114. Assuming the previous states of nodes Y and Z were a logical low, the state at both nodes Y and Z go high (shown in FIG. 2B AT 202 and 204, respectively) when the clock C2 goes high. As shown in the timing diagram, node Z changes at a significantly faster rate than does node Y. The signal at node Y changes at a slower rate than the signal at node Z because the slave latch 112 includes gates there within that consume less power since the slave latch utilizes all minimum devices. The slave latch 112 can be designed in this manner because it is not in the performance critical path.

[0016] Accordingly, in a system and method in accordance with the present invention, the multiplexor 114 outputs data from the master latch 110 when the clock C2 is active. When clock C2 is inactive (C2B), the multiplexor 114 outputs data from the slave latch 112. Therefore, in this embodiment, the multiplexor 114 receives data from the master latch 100 when the clock C2 clock is active. The multiplexor 114 outputs the data received from the master latch I/O 110 upon the clock C2 and provides the data from the slave latch 112 when the clock C2 is inactive (clock C2B). In so doing, the slave latch 112 is not part of the critical performance path of the FF 100 and its size can be minimized to reduce power consumption there within.

[0017] A system and method in accordance with the present invention optimize power consumption in a flip-flop through the use of a multiplexor for the output function. As a result, the size of the slave latch can be minimized, which reduces the overall power consumption of the flip-flop.

[0018] Although the present invention has been described in accordance with the embodiments shown, one of ordinary skill in the art will readily recognize that there could be variations to the embodiments and those variations would be within the

spirit and scope of the present invention. Accordingly, many modifications may be made by one of ordinary skill in the art without departing from the spirit and scope of the appended claims.
